CPSC 441 Computer Networks

Majid Ghaderi
Department of Computer Science
University of Calgary

Chapter 2: application layer

our goal:

- learn about protocols by examining popular application-level protocols
 - HTTP
 - SMTP / POP3 / IMAP
 - DNS

Chapter 2: outline

- 2.1 principles of network applications
- 2.2 Web and HTTP
- 2.3 Electronic mail
 - SMTP, POP3, IMAP
- **2.4 DNS**

- 2.5 P2P applications
- 2.6 Video streaming and content distribution networks

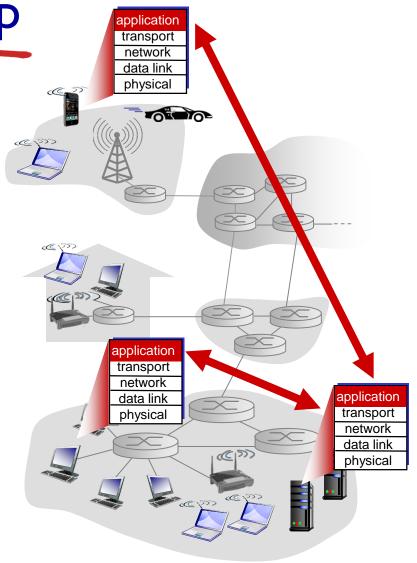

Creating a network app

write programs that:

- run on (different) end systems
- communicate over network
- e.g., web server software communicates with browser software

no need to write software for network-core devices

- network-core devices do not run user applications
- applications on end systems allows for rapid app development, propagation

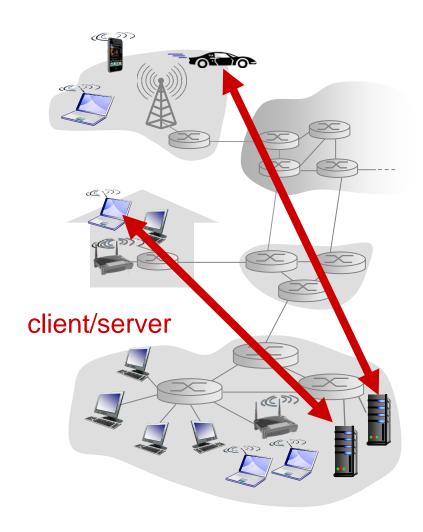

Application architectures

possible structure of applications:

- client-server
- peer-to-peer (P2P)

Client-server architecture

server:

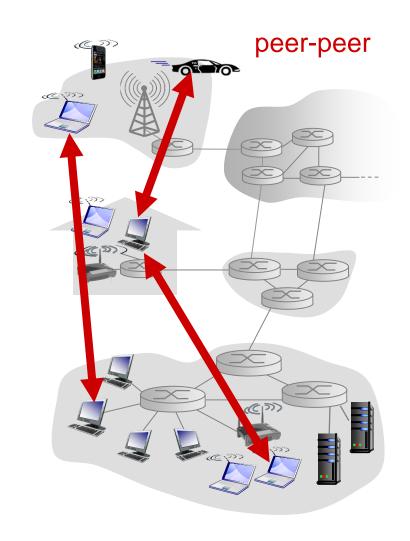

- always-on host
- permanent IP address
- data centers for scaling

clients:

- communicate with server
- may be intermittently connected
- may have dynamic IP addresses
- do not communicate directly with each other

P2P architecture

- no always-on server
- arbitrary end systems directly communicate
- peers request service from other peers, provide service in return to other peers
 - self scalability new peers bring new service capacity, as well as new service demands
- peers are intermittently connected and change IP addresses
 - complex management

Processes communicating

process: program running within a host

- within same host, two processes communicate using inter-process communication (defined by OS)
- processes in different hosts communicate by exchanging messages

clients, servers

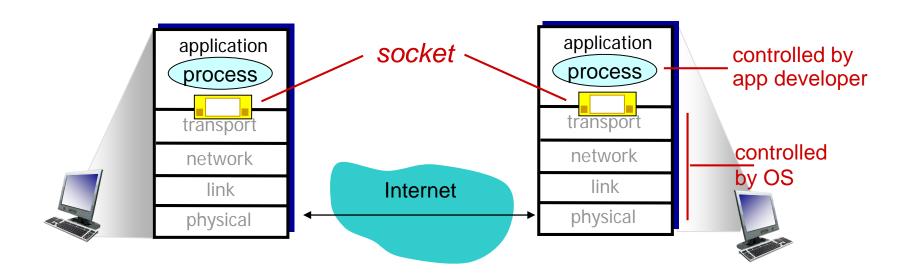

client process: process that initiates communication

server process: process that waits to be contacted

 aside: applications with P2P architectures have client processes & server processes

Sockets

- process sends/receives messages to/from its socket
- socket analogous to door
 - sending process shoves message out door
 - sending process relies on transport infrastructure on other side of door to deliver message to socket at receiving process

Addressing processes

- to receive messages, process must have identifier
- host device has unique 32bit IP address
- Q: does IP address of host on which process runs suffice for identifying the process?
 - A: no, many processes can be running on same host

- identifier includes both IP address and port numbers associated with process on host.
- example port numbers:
 - HTTP server: 80
 - mail server: 25
- to send HTTP message to gaia.cs.umass.edu web server:
 - IP address: 128.119.245.12
 - port number: 80
- more shortly...

What transport service does an app need?

data integrity

- some apps (e.g., file transfer, web transactions) require
 100% reliable data transfer
- other apps (e.g., audio) can tolerate some loss

timing

some apps (e.g., Internet telephony, interactive games) require low delay to be "effective"

throughput

- some apps (e.g., multimedia) require minimum amount of throughput to be "effective"
- other apps ("elastic apps")
 make use of whatever
 throughput they get

security

encryption, data integrity,

Transport service requirements: common apps

| application | data loss | throughput | time sensitive |
|-----------------------|---------------|--|-----------------|
| Cl (| 1 | . I C. | |
| file transfer | no loss | elastic | no |
| e-mail | no loss | elastic | no |
| Web documents | no loss | elastic | no |
| real-time audio/video | loss-tolerant | audio: 5kbps-1Mbps video:10kbps-5Mbps | |
| stored audio/video | loss-tolerant | same as above | yes, few secs |
| interactive games | loss-tolerant | few kbps up | yes, 100's msec |
| text messaging | no loss | elastic | yes and no |

Internet transport protocols services

TCP service:

- reliable transport between sending and receiving process
- flow control: sender won't overwhelm receiver
- congestion control: throttle sender when network overloaded
- does not provide: timing, minimum throughput guarantee, security
- connection-oriented: setup required between client and server processes

UDP service:

- unreliable data transfer between sending and receiving process
- does not provide: reliability, flow control, congestion control, timing, throughput guarantee, security, or connection setup,

Internet apps: application, transport protocols

| application | application layer protocol | underlying transport protocol |
|------------------------|----------------------------|----------------------------------|
| | | |
| e-mail | SMTP [RFC 2821] | TCP |
| remote terminal access | Telnet [RFC 854] | TCP |
| Web | HTTP [RFC 2616] | TCP |
| file transfer | FTP [RFC 959] | TCP |
| streaming multimedia | HTTP (e.g., YouTube), | TCP or UDP |
| • | RTP [RFC 1889] | |
| Internet telephony | SIP, RTP, proprietary | |
| | (e.g., Skype) | TCP or UDP |

Chapter 2: outline

- 2.1 principles of network applications
- 2.2 Web and HTTP
- 2.3 Electronic mail
 - SMTP, POP3, IMAP
- **2.4 DNS**

- 2.5 P2P applications
- 2.6 Video streaming and content distribution networks

Web and HTTP

First, a review...

- web page consists of base HTML-file which includes several referenced objects
- object can be HTML file, JPEG image, Java applet, audio file,...
- each object is addressable by a URL, e.g.,

www.someschool.edu/someDept/pic.gif

host name

path name

HTTP overview

HTTP: hypertext transfer protocol

- Web's application layer protocol
- client/server model
 - client: browser that requests, receives, (using HTTP protocol) and "displays" Web objects
 - server: Web server sends (using HTTP protocol) objects in response to requests

HTTP overview (continued)

uses TCP:

- client initiates TCP
 connection (creates
 socket) to server, port 80
- server accepts TCP connection from client
- HTTP messages

 (application-layer protocol messages) exchanged
 between browser (HTTP client) and Web server
 (HTTP server)
- TCP connection closed

HTTP is "stateless"

server maintains no information about past client requests

aside

protocols that maintain "state" are complex!

- past history (state) must be maintained
- if server/client crashes, their views of "state" may be inconsistent, must be reconciled

HTTP connections

non-persistent HTTP

- at most one object sent over TCP connection
 - connection then closed
- downloading multiple objects required multiple connections

persistent HTTP

 multiple objects can be sent over single TCP connection between client, server

Non-persistent HTTP

suppose user enters URL:

www.someSchool.edu/someDepartment/home.index

(contains text, references to 10 jpeg images)

- Ia. HTTP client initiates TCP connection to HTTP server (process) at www.someSchool.edu on port 80
- 2. HTTP client sends HTTP request message (containing URL) into TCP connection socket.

 Message indicates that client wants object /someDepartment/home.index
- Ib. HTTP server at host
 www.someSchool.edu waiting
 for TCP connection at port 80.
 "accepts" connection, notifying client
- 3. HTTP server receives request message, forms response message containing requested object, and sends message into its socket

Non-persistent HTTP (cont.)

5. HTTP client receives response message containing html file, displays html. Parsing html file, finds 10 referenced jpeg objects

4. HTTP server closes TCP connection.

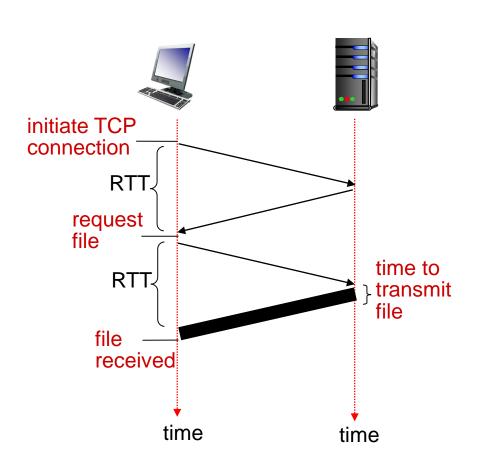

6. Steps 1-5 repeated for each of 10 jpeg objects

Non-persistent HTTP: response time

RTT (definition): time for a small packet to travel from client to server and back

HTTP response time:

- one RTT to initiate TCP connection
- one RTT for HTTP request and first few bytes of HTTP response to return
- file transmission time
- non-persistent HTTP response time =

Persistent HTTP

non-persistent HTTP issues:

- requires 2 RTTs per object
- OS overhead for each TCP connection
- browsers often open parallel TCP connections to fetch referenced objects

persistent HTTP:

- server leaves connection open after sending response
- subsequent HTTP
 messages between same
 client/server sent over
 open connection
- client sends requests as soon as it encounters a referenced object
- as little as one RTT for all the referenced objects

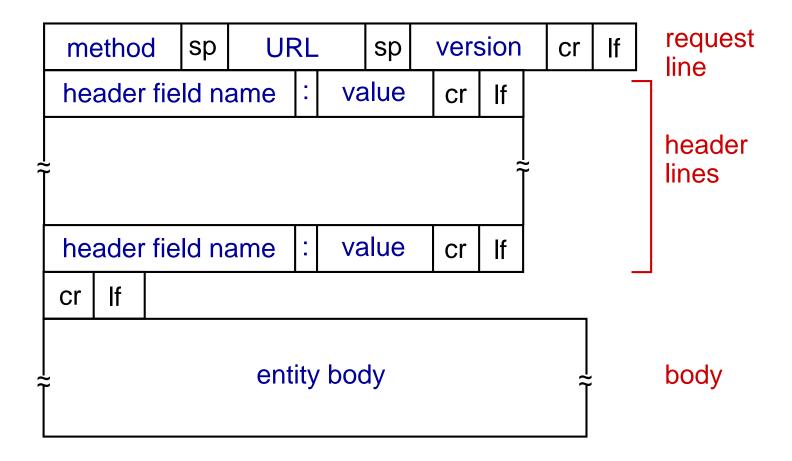

HTTP request message

- two types of HTTP messages: request, response
- HTTP request message:
 - ASCII (human-readable format)

```
line-feed character
request line
(GET, POST,
                     GET /index.html HTTP/1.1\r\n
                    Host: www-net.cs.umass.edu\r\n
HEAD commands)
                     User-Agent: Firefox/3.6.10\r\n
                     Accept: text/html,application/xhtml+xml\r\n
            header
                     Accept-Language: en-us, en; q=0.5\r\n
              lines
                     Accept-Encoding: gzip,deflate\r\n
                     Accept-Charset: ISO-8859-1,utf-8;q=0.7\r\n
                     Keep-Alive: 115\r\n
carriage return,
                     Connection: keep-alive\r\n
line feed at start
                     \r\n
of line indicates
end of header lines
```

carriage return character

HTTP request message: general format

HTTP response message

```
status line
(protocol ·
status code
              HTTP/1.1 200 OK\r\n
              Date: Sun, 26 Sep 2010 20:09:20 GMT\r\n
status phrase)
               Server: Apache/2.0.52 (CentOS)\r\n
               Last-Modified: Tue, 30 Oct 2007 17:00:02 GMT\r\n
               ETag: "17dc6-a5c-bf716880"\r\n
              Accept-Ranges: bytes\r\n
     header
               Content-Length: 2652\r\n
       lines
              Keep-Alive: timeout=10, max=100\r\n
               Connection: Keep-Alive\r\n
               Content-Type: text/html; charset=ISO-8859-1\r\n
               r\n
               data data data data ...
```

data, e.g., _ requested HTML file

HTTP response status codes

- status code appears in 1st line in server-toclient response message.
- some sample codes:

200 OK

request succeeded, requested object later in this msg

400 Bad Request

request msg not understood by server

404 Not Found

requested document not found on this server

User-server state: cookies

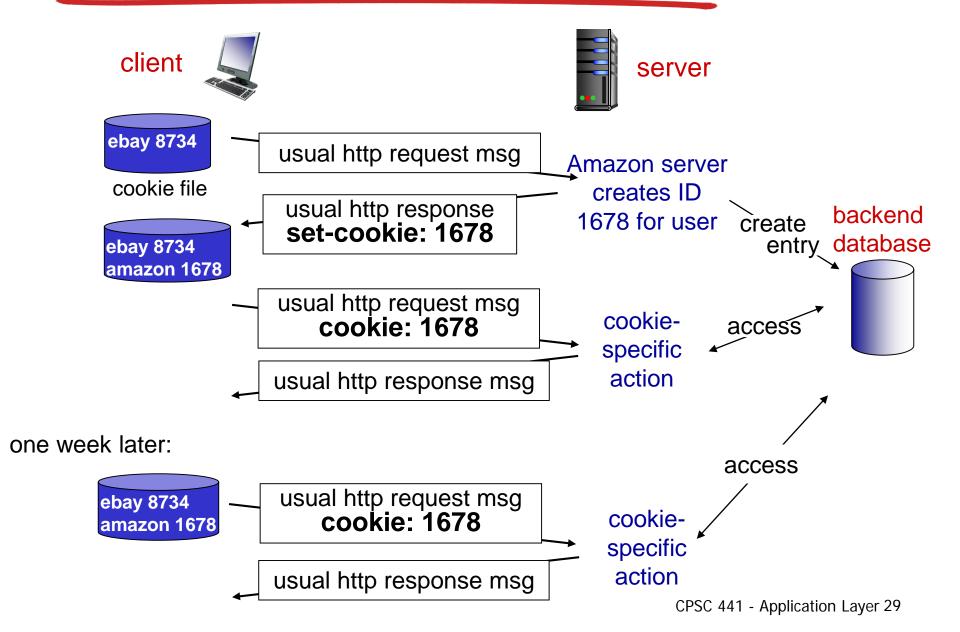

many Web sites use cookies four components:

- I) cookie header line of HTTP response message
- 2) cookie header line in next HTTP request message
- 3) cookie file kept on user's host, managed by user's browser
- 4) back-end database at Web site

example:

- Susan always access Internet from PC
- visits specific e-commerce site for first time
- when initial HTTP requests arrives at site, site creates:
 - unique ID
 - entry in backend database for ID

Cookies: keeping "state" (cont.)

Cookies (continued)

what cookies can be used for:

- authorization
- shopping carts
- recommendations
- user session state (Web e-mail)

cookies and privacy:

- cookies permit sites to learn a lot about you
- you may supply name and e-mail to sites

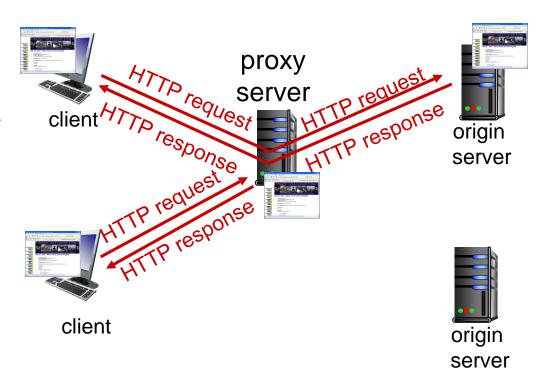

how to keep "state":

- protocol endpoints: maintain state at sender/receiver over multiple transactions
- cookies: http messages carry state

Web caches (proxy server)

goal: satisfy client request without involving origin server

- user sets browser: Web accesses via cache
- browser sends all HTTP requests to cache
 - object in cache: cache returns object
 - else cache requests object from origin server, then returns object to client

More about Web caching

- cache acts as both client and server
 - server for original requesting client
 - client to origin server
- typically cache is installed by ISP (university, company, residential ISP)

why Web caching?

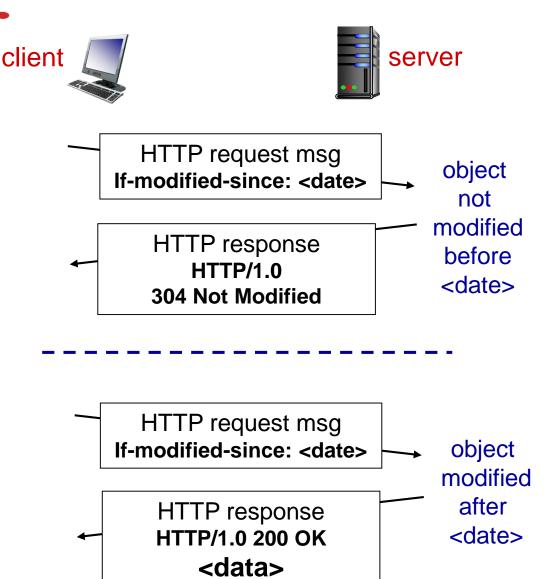

- reduce response time for client request
- reduce traffic on an institution's access link

Conditional GET

- Goal: don't send object if cache has up-to-date cached version
 - no object transmission delay
 - lower link utilization
- cache: specify date of cached copy in HTTP request

 server: response contains no object if cached copy is up-to-date:

HTTP/1.1 304 Not Modified

Chapter 2: outline

- 2.1 principles of network applications
- 2.2 Web and HTTP
- 2.3 Electronic mail
 - SMTP, POP3, IMAP
- **2.4 DNS**

- 2.5 P2P applications
- 2.6 Video streaming and content distribution networks

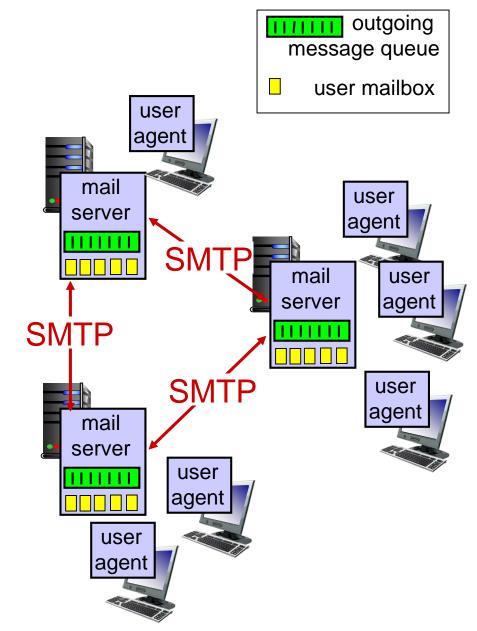

Electronic mail

Three major components:

- user agents
- mail servers
- simple mail transfer protocol: SMTP

User Agent

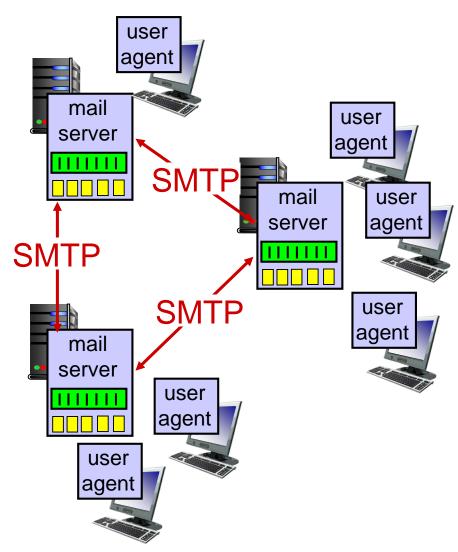

- * a.k.a. "mail reader"
- composing, editing, reading mail messages
- e.g., Outlook, Thunderbird
- outgoing, incoming messages stored on server

Electronic mail: mail servers

mail servers:

- mailbox contains incoming messages for user
- message queue of outgoing (to be sent) mail messages
- SMTP protocol between mail servers to send email messages
 - client: sending mail server
 - server: receiving mail server

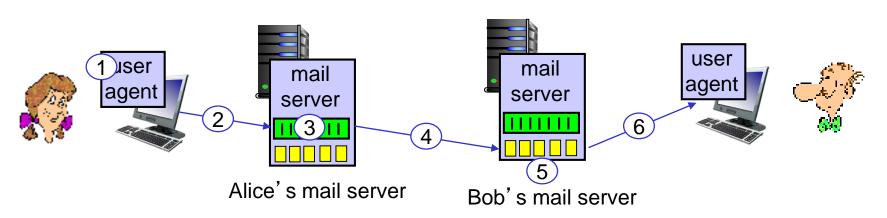

Electronic Mail: SMTP [RFC 2821]

- uses TCP to reliably transfer email message from client to server, port 25
- command/response interaction
 - commands: ASCII text
 - response: status code and phrase

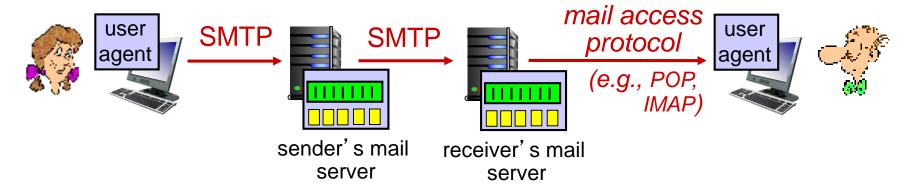

Scenario: Alice sends message to Bob

- I) Alice uses UA to compose message "to" bob@someschool.edu
- 2) Alice's UA sends message to her mail server; message placed in message queue
- 3) client side of SMTP opens TCP connection with Bob's mail server

- 4) SMTP client sends Alice's message over the TCP connection
- 5) Bob's mail server places the message in Bob's mailbox
- 6) Bob invokes his user agent to read message

Mail access protocols

- SMTP: delivery/storage to receiver's server
- mail access protocol: retrieval from server
 - POP: Post Office Protocol [RFC 1939]: authorization, download
 - IMAP: Internet Mail Access Protocol [RFC 1730]: more features, including manipulation of stored msgs on server
 - HTTP: gmail, Hotmail, Yahoo! Mail, etc.

Chapter 2: outline

- 2.1 principles of network applications
- 2.2 Web and HTTP
- 2.3 Electronic mail
 - SMTP, POP3, IMAP
- **2.4 DNS**

- 2.5 P2P applications
- 2.6 Video streaming and content distribution networks

DNS: domain name system

Internet hosts:

- IP address (32 bit) used for addressing datagrams
- "name", e.g.,www.yahoo.com -used by humans
- Q: how to map between IP address and name, and vice versa?

Domain Name System:

- distributed database implemented in hierarchy of many name servers
- application-layer protocol: hosts, name servers communicate to resolve names (address/name translation)
 - note: core Internet function, implemented as applicationlayer protocol
 - complexity at network's "edge"

DNS: services, structure

DNS services

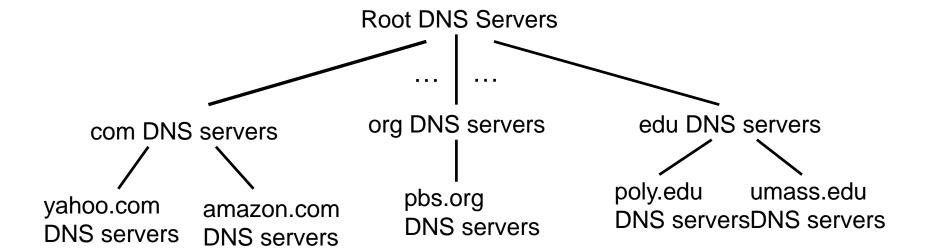

- hostname to IP address translation
- host aliasing
 - canonical, alias names
- load distribution
 - replicated Web servers: many IP addresses correspond to one name

why not centralize DNS?

- single point of failure
- traffic volume
- distant centralized database
- maintenance

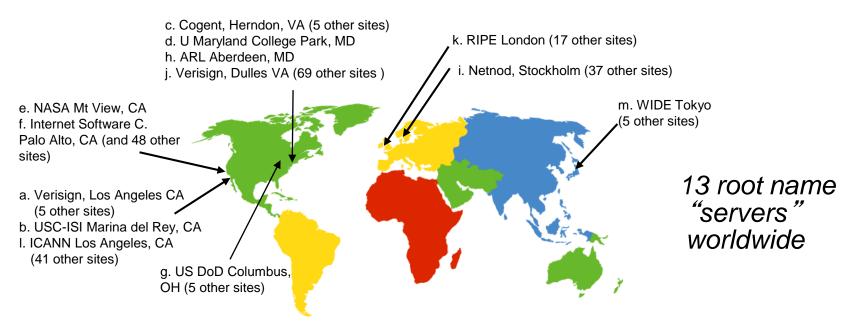

A: doesn't scale!

DNS: a distributed, hierarchical database

DNS: root name servers

- contacted by local name server that can not resolve name
- root name server:
 - either knows the name mapping
 - or, knows the name server who knows the mapping

TLD, authoritative servers

top-level domain (TLD) servers:

- responsible for com, org, net, edu, aero, jobs, museums, and all top-level country domains, e.g.: uk, fr, ca, jp
- Network Solutions maintains servers for .com TLD

authoritative DNS servers:

 organization's own DNS server(s), providing authoritative hostname to IP mappings for organization's named hosts

Local DNS name server

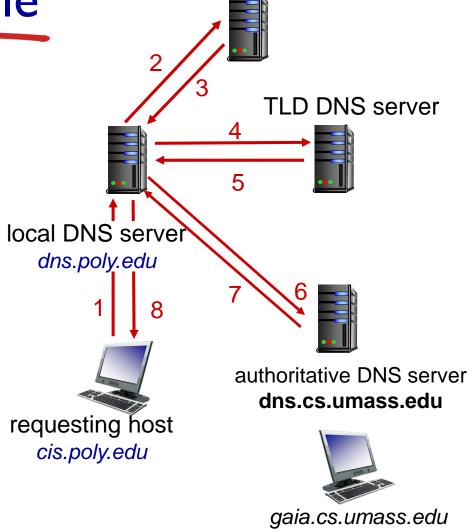

- each ISP (residential ISP, company, university) has one
 - also called "default name server"
- when host makes DNS query, query is sent to its local DNS server
 - has local cache of recent name-to-address translation pairs (but may be out of date!)
 - acts as proxy, forwards query into hierarchy

DNS name resolution example

 host at cis.poly.edu wants IP address for gaia.cs.umass.edu

iterative query:

- contacted server replies with name of server to contact
- "I don't know this name, but ask this server"

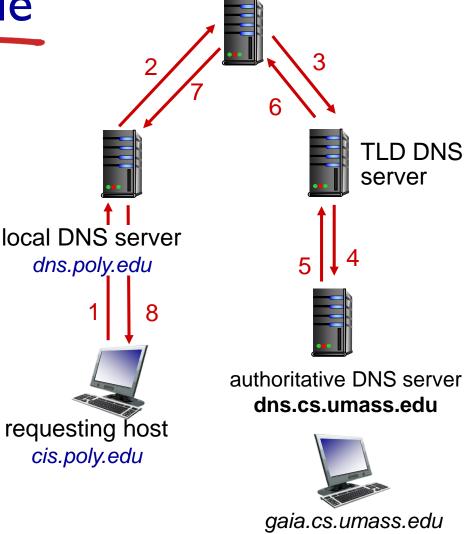

root DNS server

DNS name resolution example

recursive query:

- puts burden of name resolution on contacted name server
- heavy load at upper levels of hierarchy?

root DNS server

DNS records

DNS: distributed db storing resource records (RR)

RR format: (name, value, type, ttl)

type=A

- name is hostname
- value is IP address

<u>type=NS</u>

- name is domain (e.g., foo.com)
- value is hostname of authoritative name server for this domain

type=CNAME

- name is alias name for some "canonical" (the real) name
- www.ibm.com is really servereast.backup2.ibm.com
- value is canonical name

type=MX

 value is name of mailserver associated with name

Inserting records into DNS

- example: new startup "Network Utopia"
- register name networkuptopia.com at DNS registrar (e.g., Network Solutions)
 - provide names, IP addresses of authoritative name server
 - registrar inserts two RRs into .com TLD server: (networkutopia.com, dns1.networkutopia.com, NS) (dns1.networkutopia.com, 212.212.212.1, A)
- create authoritative server type A record for www.networkuptopia.com; type MX record for networkutopia.com

Chapter 2: outline

- 2.1 principles of network applications
- 2.2 Web and HTTP
- 2.3 Electronic mail
 - SMTP, POP3, IMAP
- **2.4 DNS**

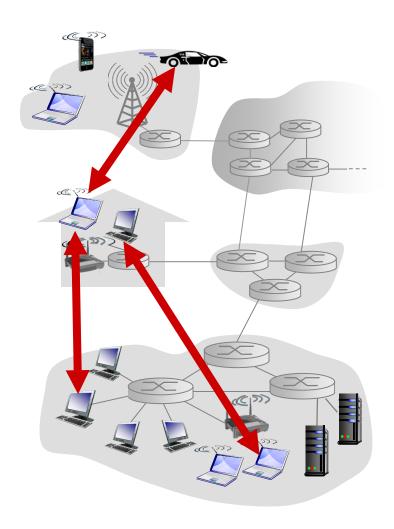

- 2.5 P2P applications
- 2.6 Video streaming and content distribution networks

P2P architecture

- no always-on server
- arbitrary end systems directly communicate
- peers are intermittently connected and change IP addresses

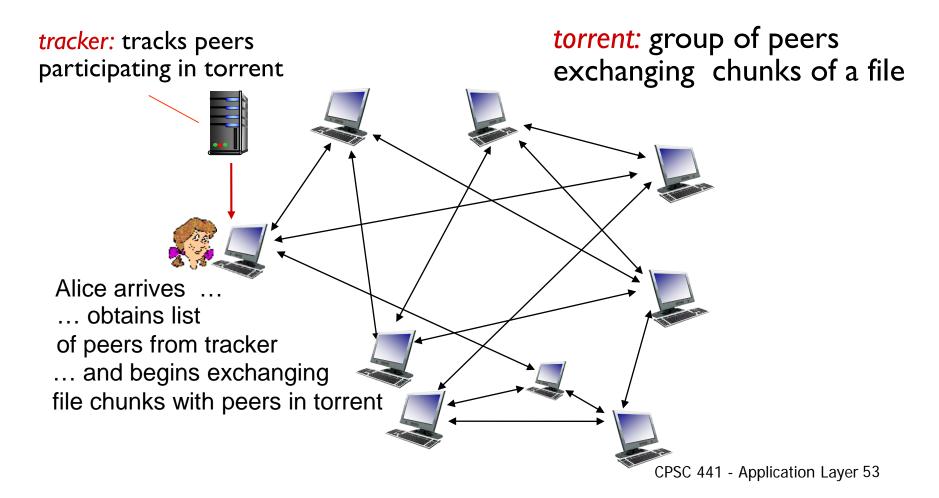

examples:

- file distribution (BitTorrent)
- VoIP (Skype)

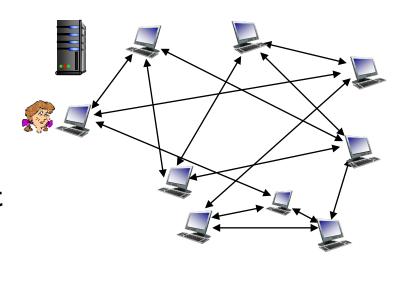

P2P file distribution: BitTorrent

- file divided into 256Kb chunks
- peers in torrent send/receive file chunks

P2P file distribution: BitTorrent

- peer joining torrent:
 - has no chunks, but will accumulate them over time from other peers
 - registers with tracker to get list of peers, connects to subset of peers ("neighbors")

while downloading, peer uploads chunks to other peers

Chapter 2: outline

- 2.1 principles of network applications
- 2.2 Web and HTTP
- 2.3 Electronic mail
 - SMTP, POP3, IMAP
- **2.4 DNS**

- 2.5 P2P applications
- 2.6 Video streaming and content distribution networks

Video Streaming and CDNs: context

- video traffic: major consumer of Internet bandwidth
 - Netflix, YouTube: 37%, 16% of downstream residential ISP traffic
 - ~1B YouTube users, ~100M Netflix users
- challenge: scale how to reach ~1B users?
 - single mega-video server won't work (why?)
- challenge: heterogeneity
 - different users have different capabilities (e.g., wired versus mobile; bandwidth rich versus bandwidth poor)
- solution: distributed, application-level infrastructure

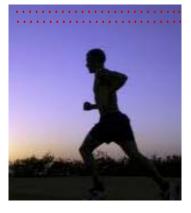

Multimedia: video

- video: sequence of images displayed at constant rate
 - e.g., 24 images/sec
- digital image: array of pixels
 - each pixel represented by bits
- coding: use redundancy within and between images to decrease # bits used to encode image
 - spatial (within image)
 - temporal (from one image to next)

spatial coding example: instead of sending N values of same color (all purple), send only two values: color value (purple) and number of repeated values (N)

frame i

temporal coding example: instead of sending complete frame at i+1, send only differences from frame i

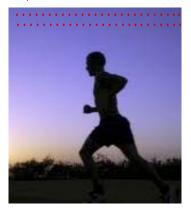

frame i+1

Multimedia: video

- CBR: (constant bit rate): video encoding rate fixed
- VBR: (variable bit rate):
 video encoding rate changes
 as amount of spatial,
 temporal coding changes
- examples:
 - MPEG I (CD-ROM) 1.5
 Mbps
 - MPEG2 (DVD) 3-6 Mbps
 - MPEG4 (often used in Internet, < I Mbps)

spatial coding example: instead of sending N values of same color (all purple), send only two values: color value (purple) and number of repeated values (N)

frame i

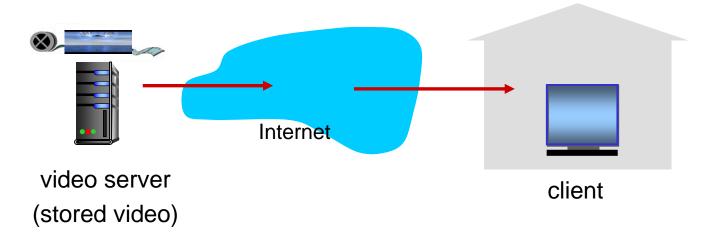

temporal coding example: instead of sending complete frame at i+1, send only differences from frame i

frame i+1

Streaming stored video:

simple scenario:

Streaming multimedia: DASH

- DASH: Dynamic, Adaptive Streaming over HTTP
- * server:
 - divides video file into multiple chunks
 - each chunk stored, encoded at different rates
 - manifest file: provides URLs for different chunks

client:

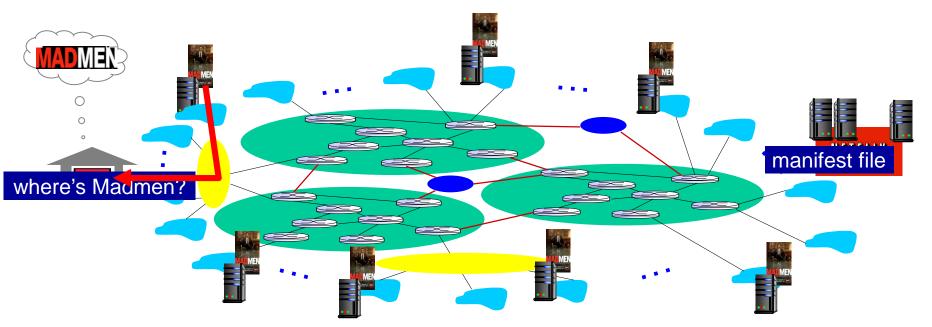

- periodically measures server-to-client bandwidth
- consulting manifest, requests one chunk at a time
 - chooses maximum coding rate sustainable given current bandwidth
 - can choose different coding rates at different points in time (depending on available bandwidth at time)

Content distribution networks

- challenge: how to stream content (selected from millions of videos) to hundreds of thousands of simultaneous users?
- solution: store multiple copies of videos at multiple geographically distributed sites (CDN)
 - push CDN servers close to users

Content Distribution Networks (CDNs)

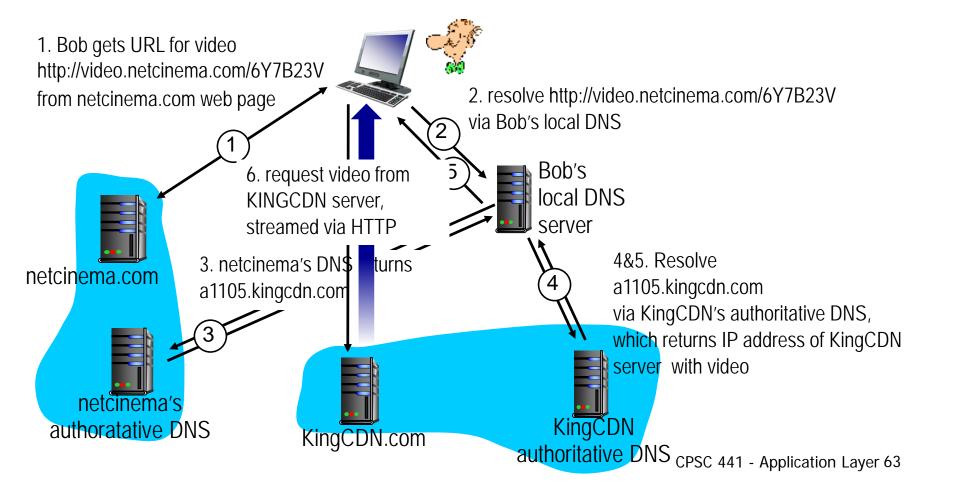

- CDN: stores copies of content at CDN nodes
 - e.g. Netflix stores copies of MadMen
- subscriber requests content from CDN
 - directed to nearby copy, retrieves content

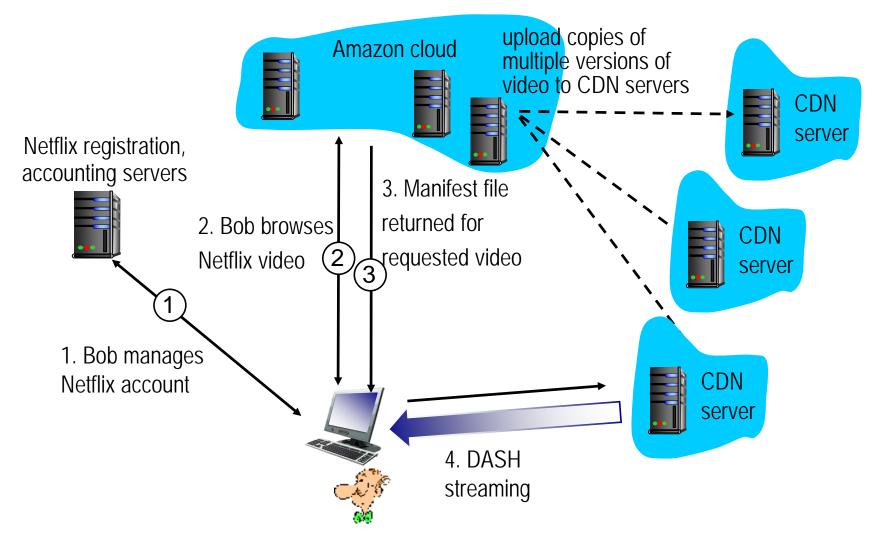

CDN content access: a closer look

Bob (client) requests video http://video.netcinema.com/6Y7B23V

video stored in CDN at a1105.Kingcdn.com

Case study: Netflix
